Quiz — Email authentication

Fillable quiz — type answers in the fields. Blank copies are already under `my-work/quizzes/`; answer them in place. Answer keys are not included.

1. Why does SMTP+TLS **not** prove the `From:` domain is authorized — what problem do SPF/DKIM/DMARC exist to solve?

2. Why does SPF check the envelope/HELO identity while DMARC still needs **alignment** with the visible `From:`?

3. Why collect `rua=` aggregate reports before `p=reject` — what fails if you skip them?

4. Why is outbound DLP/hold complementary to DMARC rather than a substitute?

5. Scenario: Marketing starts using a new ESP. DMARC aggregate shows SPF fail from new IPs. What should happen before `p=reject`, and why might SPF includes alone be insufficient?

6. Spot the bug: A DMARC record places `p=reject` before `v=DMARC1`. What happens and why?

7. Why / how (DKIM crypto): Why prefer RSA keys ≥ 2048 bits and `rsa-sha256` (not SHA-1), and when might you also publish an Ed25519 DKIM selector?
