Quiz — MailGuard Worker

Fillable quiz — type answers in the fields. Blank copies are already under `my-work/quizzes/`; answer them in place. Answer keys are not included.

Complete after the module reading. Check the separate answer key only after you attempt every item.

1. Why: Why are queue consumers often **idempotent** under at-least-once delivery?

2. Why: Name one advantage of a queue **interface** over calling a cloud SDK in every package — what fails without that boundary?

3. How: What decision vocabulary must stay shared with the Python API, and **why** does drift hurt?

4. Scenario: A worker crashes after applying a hold but before deleting the queue message. What happens on restart with at-least-once delivery, and how should the handler behave?

5. Spot the bug / why: The worker logs the full message body including attachments to stdout in production. What is wrong?

6. Trade-off: When would you keep processing in the API process instead of a worker — and what do you give up?
