Quiz — SQS + DLQ

Fillable quiz — type answers in the fields. Blank copies are already under `my-work/quizzes/`; answer them in place. Answer keys are not included.

1. How / why: If `maxAttempts=5`, does `attempt=4` go to the DLQ? Explain the threshold rule (>= vs >), and how `attempt` maps to SQS `ApproximateReceiveCount`.

2. Scenario: Handler crashes after side effects but before delete — what delivery risk remains (visibility lease), and what mitigation do you add?

3. Spot the bug: DLQ when `attempt > maxAttempts` only (strict greater). What happens to poison messages at `attempt == maxAttempts`?

4. Why: Why share a JSON schema/contract with the API instead of “whatever fields we remember”?

5. How: Name one idempotency key you could store and **why** that key (not “timestamp”) is a good choice.

6. Trade-off: Why park poison messages on a DLQ instead of deleting them after N failures?

7. Literacy: Why is ElasticMQ the default local broker here, what is the SQS max message size, and which AWS Go SDK major version should you use when wiring real SQS?
