Quiz — Cloud-share DLP

Fillable quiz — type answers in the fields. Blank copies are already under `my-work/quizzes/`; answer them in place. Answer keys are not included.

1. Why: Why does email hold miss an “anyone with the link” cloud file that never traversed SMTP as an attachment?

2. How: Name three share-link controls and, for each, what fails without it.

3. How / trade-off: What does a **presigned URL** buy you operationally — why is it **reusable** until expiry, and why can’t you revoke one raw S3 presign alone (vs signing-credential lifetime)?

4. Why: Does Secure Drop replace DMARC? Explain the different problems.

5. Scenario: A share link was emailed to the wrong person. What app-level control helps beyond waiting for expiry, and **how** must the download path be designed for that control to work?

6. Spot the bug: Audit log stores the full file bytes of every download. Problem and better design?

7. How: Why separate a **non-consuming landing** from **redemption**, and which `Referrer-Policy` value should landing/download responses send?
